This analysis focuses on usage data for two AI tools, examining individual behavior, group-level trends, job roles, employment types, and managerial status. It aims to summarize the company's current AI tool adoption, resource allocation, usage disparities across different employee segments, and potential associated risks.

Analysis Content	Objective of Analysis	Key Results
Overall adoption & subscription rate of ChatGPT vs. Copilot at the company level	To understand which tool is more widely adopted in the company, based on both usage and subscription penetration	Out of 105 total employees: 76 have used ChatGPT, 72 have used Copilot. ChatGPT has a higher overall penetration rate than Copilot.
Individual-level usage frequency comparison (active days adjusted)	To compare true usage intensity beyond raw total counts, and identify which tool users rely on more	After normalizing usage by active days: 58 users use Copilot more frequently; 28 users use ChatGPT more. Copilot shows stronger habitual use among active users.
Cross-tool usage overlap (users who use both tools)	To measure how many employees use both tools, and assess the level of AI adoption maturity	48 employees use both ChatGPT and Copilot, accounting for nearly half (46%) of total staff, indicating broad acceptance of AI tools in daily work.
Classify users into 4 tiers based on Copilot prompts: Super Active / High-Frequency / Low-Frequency / Inactive	Identify high-value users and inactive users	Clear polarization observed: high-frequency users are concentrated in non-Producer roles
Compare Producer vs. Other roles: average prompts, subscription rate, and active user proportion	Determine whether core business roles are using AI effectively	Producers have high subscription rates but low usage; Other roles have low subscription rates but high usage
Compare usage intensity and subscription coverage: Full-time vs. Outsourced employees	Identify compliance risks and permission gaps	Outsourced employees have usage intensity close to full-time staff but almost no subscription access
Compare average usage and activity: Manager vs. Non-manager roles	Assess whether management is leading by example in AI adoption	Minimal difference in usage between managers and non-managers; no clear leadership effect
Proportion of users with subscriptions but zero usage	Evaluate subscription cost waste	Approximately 20–30% of accounts are "sleeping subscriptions," indicating resource waste

At the individual level, out of 105 employees in total, 76 have used ChatGPT and 72 have used Copilot. In terms of subscription numbers, ChatGPT has a higher penetration rate in the company than Copilot. However, after dividing total messages/total prompts by active days, we find that 58 users use Copilot more frequently, while 28 users use ChatGPT more. Meanwhile, 48 employees in the company use both AI tools, accounting for nearly half of the total staff. In terms of category differences， first, there is a clear resource misallocation: Producer roles, despite holding 81.0% Copilot subscription coverage, use the tool only one-third as much as non-Producer roles (21.6 vs. 71.0 prompts per person), with only 19.0% of Producer users classified as high-frequency or super-active, alongside a 10.5% dormant user rate, indicating significant "subscribed but unused" licenses. Second, contingent workers show usage intensity nearly on par with full-time employees (70.2 vs. 64.3 average Copilot prompts) but have negligible subscription coverage (0.07%). Third, managers receive slightly higher subscription

coverage (75.7% vs. 69.4%) but exhibit no meaningful difference in usage intensity compared to non-managers (61.1 vs. 63.9 average prompts), suggesting the AI tools have not yet been embedded into management workflows.

Based on the analysis results, we draw the following conclusions:

1. Although the AI tool subscription rate is high, usage remains low among many employees — especially those in Producer roles — meaning subscriptions are not being effectively leveraged in daily work.
2. Contingent worker show significantly higher per capita AI usage despite not having official subscriptions. This indicates a substantial amount of unregulated AI use, which the company should address to promote compliant usage and safeguard data security and work quality.
3. There is almost no difference in AI usage between managers and non-managerial employees. Managers should take a leading role in modeling and encouraging AI adoption across teams.
4. AI usage varies drastically across work groups, with adoption heavily concentrated in only a few teams. Management should guide more balanced AI usage across all groups to drive overall operational quality.

This analysis of AI tool usage reveals three key issues with the company's current AI rollout: resource misallocation, permission imbalance, and insufficient adoption.

1. Resource Misallocation: Subscription resources are skewed toward Producer roles, yet the highest-value users are in other job categories.
2. Permission Imbalance: Contingent workers use AI tools frequently but lack compliant subscriptions, posing data security risks.
3. Insufficient Adoption: Neither management nor core roles use AI deeply, leaving the full value of these tools untapped.

Overall, the company needs to reallocate subscription resources, provide compliant access for contingent workers, and deliver scenario-based training for Producers and managers to unlock AI's true potential and drive efficiency gains across the organization.
